

Land-use influence on Mediterranean perennial swards of *Poa bulbosa*: a case study in the International Tagus Region

Sílvia Ribeiro (*), Paula Gonçalves (**) & M. Dalila Espírito-Santo (*)

Abstract: Ribeiro, S., Gonçalves, P. & Espírito-Santo, M.D. *Land-use influence on Mediterranean perennial swards of Poa bulbosa: a case study in the International Tagus Region. Lazaroa 33: 51-64 (2012).*

Pastureland abandonment or intensification of livestock activity change the floristic patterns of Mediterranean perennial swards which are very important to the conservation of some bird species. The objectives of this study are: 1) to recognise floristic patterns in Mediterranean perennial swards of *Poa bulbosa*; 2) to identify the communities that configure the European priority habitat 6220* (Pseudo-steppe with grasses and annuals of the *Thero-Brachypodietea*); 3) to assess the effects of land-use management on the floristic composition of these communities. Field research was conducted in central eastern and south eastern main land Portugal. Vegetation sampling was carried out in 2009-2010 on 9 sward sites, following the phytosociological concepts. Classification and ordination of relevés were obtained by Two Way Indicator Species Analysis (TWINSPAN), Canonical Correspondence Analysis (CCA) and Detrended Canonical Correspondence Analysis (DCCA). Monte Carlo Permutation Tests were performed to analyse differences in floristic patterns. Livestock load, stoniness and land-use history of the last 10 years were selected as the key variables that best explain the ordination model. The absence of extensive livestock grazing results in a reduction of *Trifolium subterraneum*-dominated areas and in a density/cover reduction of *Poa bulbosa*-dominated areas. High livestock loads change the floristic patterns of Mediterranean short swards by favouring species of the *Stellarietea mediae* class. The control of woody vegetation through grazing or cutting is a key conservation measure.

Keywords: conservation, floristic patterns, management, Mediterranean short swards, priority habitat.

Resumen: Ribeiro, S., Gonçalves, P. & Espírito-Santo, M.D. *Influencia del manejo en los pastizales de Poa bulbosa: estudio en la región internacional del Tajo. Lazaroa 33: 51-64 (2012).*

El abandono de los pastizales o la intensificación de la actividad ganadera cambia los patrones florísticos de pastizales mediterráneos perennes que son muy importantes para la conservación de algunas especies de aves. Los objetivos de este estudio son: 1) reconocer los patrones florísticos mediterráneos en pastizales de *Poa bulbosa*; 2) identificar las comunidades que configuran el hábitat prioritario Europeo 6220* (Zonas subestépicas de gramíneas y anuales de *Thero-Brachypodietea*); 3) evaluar los efectos de la gestión del uso del suelo en la composición florística de estas comunidades. El trabajo de campo se llevó a cabo en el centro-este y sudeste de la zona continental de Portugal. Los inventarios de dicha vegetación se realizaron en 2009-2010 en nueve localidades, siguiendo los conceptos fitosociológicos. La clasificación y ordenación de los inventarios se ha realizado por medio de análisis multivariantes (TWINSPAN, CCA y DCCA). Además se realizó un test de permutación de Monte Carlo para analizar las diferencias en los patrones florísticos. La carga ganadera, la pedregosidad y la historia de uso del territorio de los últimos 10 años fueron seleccionadas por dicho test, como las variables que mejor explican el modelo de ordenación. La reducción del pastoreo extensivo disminuye las áreas dominadas por *Trifolium subterraneum* y la densidad/cobertura de aquellas áreas dominadas por *Poa bulbosa*. Las altas cargas ganaderas, por el contrario, cambian los patrones florísticos favoreciendo a las especies de la clase *Stellarietea mediae*. El control de la vegetación leñosa a través del pastoreo o corte es una medida clave para su conservación.

Palabras clave: Conservación, Patrones florísticos, Gestión, Praderas perennes mediterráneas, Hábitat prioritario.

INTRODUCTION

Mediterranean natural and semi-natural grasslands are amongst the protected habitats in Europe, contributing to the so-called cultural landscapes (SAN MIGUEL, 2008). Pseudo-steppe with grasses and annuals of the *Thero-Brachypodietea* (Natura 2000 code: 6220*; EC, 2007) are a priority habitat under the European Union Habitats Directive (COUNCIL DIRECTIVE 92/43/EEC on the conservation of natural habitats and of wild fauna and flora).

Due to its dependence on Mediterranean climate, the 6220 habitat occurs mainly in the Mediterranean region. In Portugal five subtypes were considered within this habitat type (ICNB, 2006). The Mediterranean perennial swards of *Poa bulbosa* (Class *Poetea bulbosae*) are included in subtype 2 (ICNB, 2006).

Studies on Mediterranean perennial short swards of the *Trifolio subterranei-Periballion alliance* in the Iberian Peninsula, at both the descriptive and/or management level, were mainly developed by RIVAS GODAY & RIVAS MARTÍNEZ (1963), RIVAS GODAY (1964), RIVAS GODAY & LADERO (1970), AMOR & al. (1993), LADERO & al. (1994) and more recently by GALÁN & al. (2000), and CANO & al. (2007). These communities were also studied by SANTOS & al. (1988), DE LA FUENTE (1985), IZCO & al. (2000), ROMERO & al. (1994), LOIDI ARREGUI & al. (1997), MONSERRAT & FILLAP (1999), AGUIAR (2000), CANTÓ (2004), SÁNCHEZ RODRÍGUEZ & al. (2006) and SILVA & al. (2009) in more restricted areas.

This study focuses on the *Trifolio subterranei-Periballion* alliance which is often linked to the dehesa system. This alliance occurs throughout the silicicolous thermo- to supramediterranean dry to lower subhumid territories. These Mediterranean perennial swards dry up in early summer, but grow back fast after the first autumn rains and remain green and fertile during winter (RIVAS-MARTÍNEZ, 2007). They are found on both oligotrophic and eutrophic soils (SAN MIGUEL, 2008) which results in a floristic composition intruded by a large number of therophytes of the *Tuberarietea guttatae* class (oligotrophic soils) or of the *Stellarietea mediae* class (eutrophic soils). They

are also especially linked to the transhumance migration routes, mainly for sheep, that lead to the mountain summer pastures or those that connect the altitudinal areas to the autumn-winter-spring pastures of the lower plains (GALÁN & al., 2000).

The Mediterranean perennial swards of *Poa bulbosa* usually occur in a mosaic pattern with a wide variety of other plant communities. They are very positively selected by the European rabbit (*Oryctolagus cuniculus*; SAN MIGUEL, 2008) that has been identified as a keystone species to the Iberian ecosystem (IUCN, 2011a), as prey for specialist predators (VIRGOS & al., 2005), as a landscape modeller (DELIBES & al., 2000; WARD, 2005) and as an agent for increasing soil fertility (WILLOTT & al., 2000).

The International Tagus Region - border section of the Tagus River between Portugal and Spain, confining tributary valleys and adjacent plateaux - is well known for its importance in avian conservation. Part of this territory has been classified as a Portuguese natural park and as a Special Protection Area under the European Union Birds Directive (DIRECTIVE 2009/147/EC on the conservation of wild birds).

Endangered species such as the Iberian imperial eagle (*Aquila adalberti*; Conservation Status in Portugal: Critically Endangered (CABRAL & al., 2005), Bonelli's eagle (*Hieraetus fasciatus*; Conservation Status in Portugal: Endangered (CABRAL & al., 2005), the black vulture (*Aegypius monachus*; Conservation Status in Portugal: Critically Endangered (CABRAL & al., 2005), the golden eagle (*Aquila chrysaetos*; Conservation Status in Portugal: Endangered (CABRAL & al., 2005) and the Egyptian vulture (*Neophron percnopterus*; Conservation Status in Portugal: Endangered (CABRAL & al., 2005) occur in the study area (ICNB, 2007) and depend, to a higher or lesser degree on wild rabbit and, consequently, on *Poetalia bulbosae* swards.

This study aims to investigate the land-use influence on the floristic composition of Mediterranean perennial swards of *Poa bulbosa* in the International Tagus Region.

MATERIAL AND METHODS

STUDY AREA

Although fieldwork covered a total area of approximately 28700 km² in central eastern and south eastern main land Portugal, only in the International Tagus Natural Park and neighbouring area were requirements met to assess the effects of land-use management on Mediterranean short swards of *Poetea bulbosae*. Sampling of these communities was carried out in the International Tagus Natural Park and adjacent areas (Figure 1) on siliceous rock (mainly schist). According to the biogeographic typology of RIVAS MARTÍNEZ (2007) the sampled area is included in the Western Mediterranean Subregion, Mediterranean West Iberian Province (Lusitan-Extremadurean Subprovince).

The altitudes of the surveyed sites range from 135 to 310 m above sea level. These sites fall within the upper thermomediterranean to lower mesomediterranean thermotype and

upper dry to lower subhumid ombrotype climatic belts (RIVAS-MARTÍNEZ, 2005; MONTEIRO-HENRIQUES, 2010).

The communities under study occur in patches throughout extensive scrublands and dehesas which were intensively farmed with cereals in 1930-1940 (CHAMBINO, 2000). Today forestry prevails in the study area, along with extensive sheep, goat, cattle and, to a lesser degree, pig grazing; olive growing and polyculture is concentrated around villages and sport hunting (especially big game sport hunting) is widespread (CARVALHINO, 2004).

The sampled communities are related to the corkoak *Sanguisorbo agrimonioidis-Quercus suberis* S. and the holmoak *Pyro bourgaeanae-Quercus rotundifoliae* S. climatophilous series.

Botanical nomenclature follows CASTROVIEJO & al. (1986-2010), FRANCO (1971, 1984), FRANCO & ROCHA AFONSO (1994, 1998) and PIZARRO (1995). Bioclimatological, Biogeographical and Syntaxonomical typology was checked according to RIVAS-MARTÍNEZ (2007).

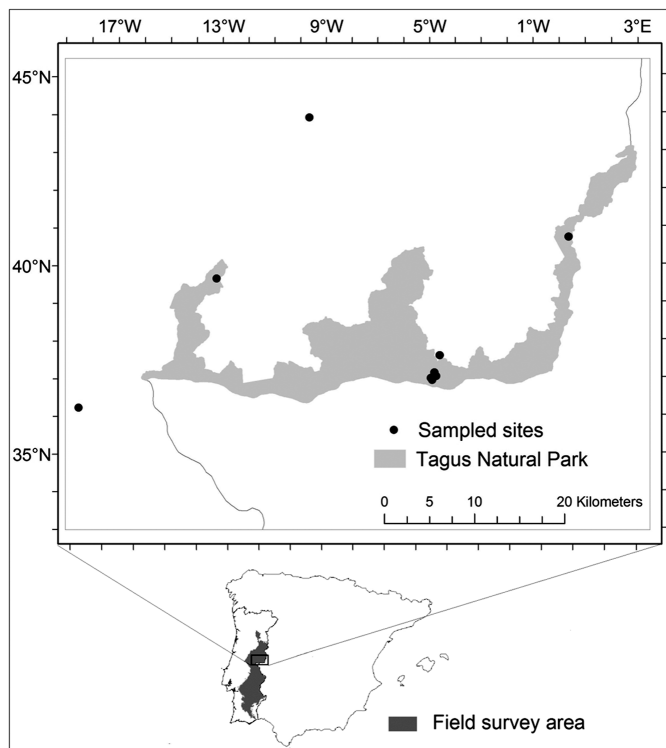

Figure 1. – Study area and location of the sampled Mediterranean short sward sites.

SAMPLING DESIGN AND DATA COLLECTION

Field sampling was carried out on 9 Mediterranean short sward sites (26 relevés), following the phytosociological concepts of BRAUN-BALANQUET (1964, 1979) modified by GÉHU & RIVAS-MARTÍNEZ (1981). The communities were surveyed using the minimum area method (the smallest area which adequately represents community composition) in line with MUELLER-DOMBOIS & ELLENBERG (1974). As suggested by CHYTRÝ & OTÝPKOVÁ (2003), OTÝPKOVÁ & CHYTRÝ (2006) and DENGGLER & al. (2009), the representative plot size of a homogenous floristic composition was set at 4 m² in order to reduce the potential effects of different plot sizes in classification and ordination analyses. Each taxon's percentage cover was recorded to allow for multivariate analysis (PODANI, 2006). The percent cover of bryophytes was also registered for each relevé.

Predictor variables were recorded for each herb community, including both qualitative and quantitative environmental and land-use variables. These predictor variables were assigned to two groups: (i) environmental, (ii) land-use.

The environmental factors include: latitude, longitude, altitude, aspect, slope, rock type, percentage of stone (stoniness), soil texture, soil humidity and soil depth.

Land-use influence was evaluated by using: a) livestock load and b) regularity of grazing or livestock permanence. Four classes were considered for livestock load: 1 - Very light (very lightly grazed); 2 - Light (extensive grazing); 3 - High (all year round permanence zones and high animal load with high animal density) and; 4 - Very high (penned and overloaded livestock areas). Four classes were defined for regularity of grazing or livestock permanence: 1 - Very irregular use during 6 months; 2 - Irregular use during 6 months; 3 - Regular use during 6 months and 4 - Regular uses all year round.

DATA ANALYSIS

The data set includes 26 relevés and 159 species. A hierarchical polythetic divisive classification was performed on the species data with

Twinspan for Windows version 2.3 (WinTWINS) (HILL & SMILAUER, 2005). Rare species were not excluded from the analysis and all species maintained default user weight (1.0). Nine pseudospecies cut levels were specified: 0 (0-9%), 10 (10-19%), 20 (20-29%), 30 (30-39%), 40 (40-49%), 50 (50-59%), 60 (60-69%), 70 (70-79%), 80 (80-100%).

The major groups defined through Twinspan were tested with Monte Carlo Permutation Test (9999 permutations) in order to test the statistical significance of these groups.

According to JONGMAN & al. (1995) a unimodal response can be detected by a Detrended Correspondence Analysis (DCA) if the gradient lengths exceed 2 SD. As this occurred in this study, the relationships between a species' occurrence and the main explanatory variables were assessed through Detrended Canonical Correspondence Analysis (DCCA) to avoid the arch effect. All data were log-transformed log (x+1) to improve normality. In order to detect collinearity between the explanatory variables, a forward selection (BORCARD & al., 1992; HEIKKINEN & al., 2004) was performed by the Monte Carlo Permutation Test (9999 permutations) in a previous CCA analysis which resulted in the exclusion of variables that did not contribute significantly ($p < 0.05$) to the ordination pattern. The variance inflation factors for the explanatory variables were examined to detect collinearity.

All of the above analyses were performed with the CANOCO 4.5 software (TER BRAAK & ŠMILAUER, 2002). The software JUICE 7.0.56 (TICHÝ, 2002) was used to edit, analyse and produce the phytosociological tables.

RESULTS

CLASSIFICATION OF RELEVÉS

The Twinspan classification (Figure 2) resulted in the definition of 14 groups. Since WinTWINS sets the minimum group size for division at 3, Divisions VII and X were determined by the authors. Division I ($\lambda = 0.484$) separates areas used

Figure 2. – Twinspan classification dendrogram.

continuously all year round - feeding and/or livestock areas - from those used regularly or irregularly during 6 months of the year. *Poa bulbosa*, *Herniaria scabrida* and *Logfia gallica* are exclusive negative preferentials occurring in two thirds of the sampled plots. Division II ($\lambda = 0.391$) divides penned livestock areas from communities with a cover-abundance of *Poa bulbosa* of 20 % or more. *Erodium moschatum*, *Amaranthus* sp. and *Sisymbrium officinale* are faithful to the first group. Division III ($\lambda = 0.667$) isolates the *Hordeum leporinum*-dominated Group 14. Division IV ($\lambda = 0.559$) defines Group 1 - a *Stellarietea mediae* community with *Polygono-Poetea annuae* species. Division V ($\lambda = 0.347$) clusters nine of the ten relevés with *Erodium botrys* in the 'negative group' and most of the relevés with *Hypochaeris glabra*, *Tolpis barbata* and *Trifolium glomeratum* in the 'positive' group. Division VI ($\lambda = 0.607$) results in the definition of Group 13 (corresponding to a fragmented *Pulicario-Agrostietum salmanticae* association with *Stellarietea mediae* companion species). Division VII separates a *Stellarietea mediae* community dominated by *Geranium molle* and *Capsella bursa-pastoris* with some species of the *Hordeion leporini* alliance (Group 2) from *Stellarietea mediae* community dominated by *Capsella bursa-pastoris* (Group 3). Division VIII ($\lambda = 0.369$) separates the abandoned Mediterranean short sward communi-

ties (*Poa bulbosa*-*Trifolietum subterranei*) from the lightly grazed Mediterranean short sward community (Group 6). Division IX ($\lambda = 0.440$) sets Group 10 apart - edge community of extensively grazed Mediterranean short swards rich in *Helianthemetea guttatae-Stellarietea mediae* species and with *Poa bulbosa*. Division X results in two Groups: 11 (*Stellarietea mediae* community); and 12 (*Echium plantagineum* community). Division XI ($\lambda = 0.580$) distinguishes the *Poa bulbosa*-*Trifolietum subterranei* association according to the dominant species: *Trifolium subterraneum* in Group 4 and *Poa bulbosa* in Group 5. Division XII ($\lambda = 0.474$) delimits Group 9, an edge community of abandoned Mediterranean short swards rich in *Helianthemetea guttatae-Stellarietea mediae* species and with *Poa bulbosa*. Division XIII ($\lambda = 0.457$) divides the lightly grazed *Trifolium subterraneum*-dominated Mediterranean short swards (Group 7) from the lightly grazed *Poa bulbosa*-dominated ones (Group 8). Twinspan divisions, indicator species and defined groups with respective syntaxa are presented in Table 1.

The 14 groups were clustered into five sets (Sets A to E) that reflect their land-use history over the last decade: Set A- Panned livestock areas of Mediterranean short swards for at least 5 years (PLAMS); Set B - Abandoned Mediterranean short swards (rarely grazed by livestock) for

Table 1
Twinspan divisions, indicator species and defined groups with respective syntaxa

Division	'Negative' Group Indicator(s)	'Positive' Group Indicator(s)	Group	Syntaxa
I	<i>Poa bulbosa</i> (1)	<i>Bromus</i>	-	-
II	<i>Erodium moschatum</i> (1)	<i>hordeaceus</i> (1)	-	-
III	<i>Agrostis pourretii</i> (1)		14	<i>Hordeum leporinum</i> community
IV	<i>Anarrhinum bellidifolium</i> (1)		1	<i>Stellarietea mediae</i> community with <i>Polygono-Poetea annuae</i> species
V		<i>Hypochaeris glabra</i> (1) <i>Spergularia purpurea</i> (1) <i>Trifolium glomeratum</i> (1) <i>Tolpis barbata</i> (1)	-	-
VI	<i>Capsella bursa-pastoris</i> (1)		13	Fragmented <i>Pulicario-Agrostietum salmanticaei</i> association with <i>Stellarietea mediae</i> companion species
VII			2	<i>Stellarietea mediae</i> community dominated by <i>Geranium molle</i> and <i>Capsella bursa-pastoris</i> with some species of the <i>Hordeion leporini</i> alliance
			3	<i>Stellarietea mediae</i> community dominated by <i>Capsella bursa-pastoris</i>
VIII	<i>Spergula arvensis</i> (1) <i>Stachys arvensis</i> (1) <i>Coronilla dura</i> (1)	<i>Tuberaria guttata</i> (1)	6	<i>Poo bulbosae-Trifolietum subterranei</i>
IX		<i>Andryala integrifolia</i> (1)	10	Edge community rich in <i>Helianthemetea guttatae-Stellarietea mediae</i> species and with <i>Poa bulbosa</i>
X			11, 12	<i>Stellarietea mediae</i> community and <i>Echium plantagineum</i> community (<i>Echium plantaginei-Galactition tomentosae</i>)
XI	<i>Aira caryophylla</i> (1)		4, 5	<i>Poo bulbosae-Trifolietum subterranei</i>
XII		<i>Anarrhinum bellidifolium</i> (1)	9	Edge community rich in <i>Helianthemetea guttatae-Stellarietea mediae</i> species and with <i>Poa bulbosa</i>
XIII		<i>Anagallis arvensis</i> (1)	7, 8	<i>Poo bulbosae-Trifolietum subterranei</i>

at least 10 years (AMS); Set C - Lightly grazed Mediterranean short swards in the last 10 years (LGMS); Set D - Trampled and ruderalised Mediterranean short swards in the last 10 years (TRMS); Set E - Feeding and/or resting livestock areas of Mediterranean short swards for at least 10 years (FRLAMS) (Table 2).

Groups 4, 5, 6, 7 and 8 are related with the *Poo bulbosae-Trifolietum subterranei* silicicolous phytosociological association (Table 3). This association configures the European priority habitat 6220* (Pseudo-steppe with grasses

and annuals of the *Thero-Brachypodietea*). *Trifolium subterraneum*-dominated Groups 4 and 7 are much less frequent than *Poa bulbosa*-dominated Groups 5, 6 and 8. The floristic composition of groups 6, 7 and 8 are a result of extensive grazing mainly by sheep and to a lesser degree by goats and/or cattle, while Groups 4 and 5 correspond to *Poa bulbosa* swards rarely grazed by livestock.

An alphabetical list of abbreviated taxa used in the current text and in the phytosociological table is shown in Appendix I.

Table 2

Relationship between Twinspan sets and land-use variables. Livestock load: 1- Very light; 2- Light; 3 - High; 4 - Very high. Regularity of grazing or livestock permanence: 1 - Very irregular use during 6 months; 2 - Irregular use during 6 months; 3 - Regular use during 6 months and 4 - Regular use all year round.

Twinspan set/ Land-use history of the last 10 years	Group	Livestock load	Regularity of grazing of or livestock permanence
A (PLAMS)	1	4	2
	2	4	2
	3	4	2
B (AMS)	4	1	1
	5	1	1
C (LGMS)	6	2	3
	7	2	3
	8	2	3
D (TRMS)	9	1	2
	10	2	4
E (FRLAMS)	11	3	4
	12	3	4
	13	3	4
	14	3	4

Monte Carlo Permutation Test results for the Twinspan Sets (Table 4) show a highly significant difference ($p < 0.01$) between the penned areas (Set A) and both the Mediterranean short sward communities (Sets B and C) and the edge communities (Set D). The feeding and/or resting areas (Set E) also present a highly significant difference when compared with both Sets B and C. A highly significant difference is also observed between Sets C and D.

A significant difference ($p < 0.05$) was obtained between Sets A and E and between Sets D and E.

RELATIONSHIP BETWEEN SPECIES COMPOSITION DATA AND ECOLOGICAL VARIABLES

The floristic and ecological patterns of the data were identified through the CCA and DCCA analyses.

Following the Monte Carlo Permutation Test carried out in a previous CCA ($p < 0.05$) only environmental and land-use variables such as livestock load, regularity of grazing or livestock permanence and stoniness were selected as the

key variables that best are related to the ordination model.

The DCCA ordination diagram (Figure 3) shows the relationship between the sets obtained previously by the TWINSpan classification with the selected environmental and land-use variables. The first two axes of the DCCA explain 14.4% of species variation that are explained in 67.3% of the ecological variables selected. The first canonical axis eigenvalue is 0.441 with $p = 0.001$.

The relationship between species composition data and ecological variables shows:

- Axis 1 portrays the degree of naturalness of the five sets defined through the Twinspan classification by separating the feeding and/or resting livestock areas from the other sampled plots, thus reinforcing the first's older land-use history and higher intensity of use. The abandoned swards of the International Tagus region classified as Twinspan's Set B, has been placed farthest away from the samples with the highest intensity of use and highest animal load on the positive end of the axis.

- Axis 2 reveals a stoniness (soil depth) gradient that separates penned livestock areas from the rest as places with deeper soil depth were chosen to facilitate fence installation.

- Set B of Twinspan has a higher percentage cover of bryophytes and is strongly correlated to the presence of rock outcrops which indicates lack of intervention for several years and low agricultural aptitude respectively.

DISCUSSION

The main gradient resulting from the combination of livestock load, regularity of grazing or livestock permanence and land-use history of the last 10 years is responsible for the order of the 14 groups defined in the Twinspan dendrogram.

The floristic changes discovered in the *Poa bulbosae-Trifolietum subterranei* silicicolous phytosociological association resulted in the description of different subassociations by RIVAS GODAY & LADERO (1970) and LADERO & al. (1994). None of these subassociations is well represented in the study sites.

D					0.0179*
E					

Poa bulbosa is more abundant in lightly grazed Mediterranean short swards (Set C with an average cover of 71.25 %) than in abandoned Mediterranean short swards (Set B with an average cover of 60.00 %) and edge communities rich in *Helianthemetea guttatae* or *Stellarietea mediae* species and with *Poa bulbosa* (Set D with an average cover of 30 %). This species has

disappeared from feeding and/or resting areas (Set E) and is residual in holding pens (Set A) where it occurs in one of the three sampled plots with an abundance of 2 %. According to RIVAS GODAY (1964) overgrazing of *Poa bulbosa* communities increases the nitrate levels, resulting in the reduction of palliative species and their replacement by nitrophilous species of low forage interest, thus lowering the feeding value for livestock. The ability of herbivores to select better quality components of the swards has also been documented in other studies (HEADY, 1964; HEJCMAN & al., 2008). If nitrification is too great these swards change to *Chenopodietalia muralis* communities (AMOR & al., 1993). The same was found in this study. The communities of *Stellarietea mediae*, *Echium plantagineum* and *Hordeum leporinum* identified at the feeding and/or resting areas and penned livestock areas suggest that the higher nitrate levels are the main reason

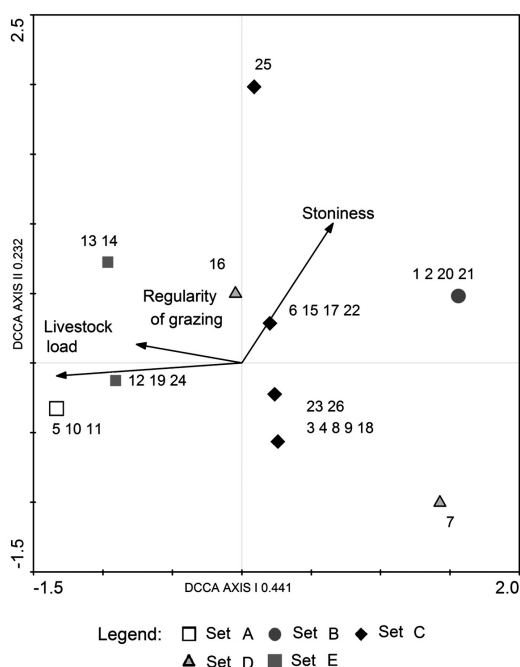

Figure 3. – Detrended Canonical Correspondence Analysis (DCCA). Biplot with samples and ecological variables. A, B, C, D and E: sets resulting from the TWINSPLAN classification.

for the disappearance or residual presence of *Poa bulbosa*.

Poa bulbosa is the only *Poetea bulbosae* species present in Set D. The similarity between this group and Set B ($p = 0.1332$) is probably due to the smaller difference in average percentage cover of *Poa bulbosa* - 30.00 % - as opposed to the greater difference - 41.25% - observed between Sets C and D ($p = 0.0001$). This also holds true for Sets B and C ($p = 0.1204$) with an 11.25% difference. A highly significant difference occurs exclusively between extensively grazed and trampled and ruderalised plots which seem to result from a differential use by livestock.

There is a marked difference between *Trifolium subterraneum*-dominated areas and *Poa bulbosa*-dominated areas:

- *Trifolium subterraneum*-dominated areas may be expanded through extensive grazing as clover seeds are buried through sheep trampling (RIVAS GODAY, 1964). The annual legumes that constitute these patches disappear in autumn/winter, which they pass in the form of seed, indicative

of a phenological variation in the floristic composition of these communities also identified by RUIZ & PÉREZ (2009).

- extensive grazing favours the abundance of *Poa bulbosa* in *Poa bulbosa*-dominated areas by promoting reproduction while the consequent nutrient input helps to sustain a higher plant density and higher biomass production.

Extensive live stock grazing can thus improve these short swards not only in surface area but also in productivity and biomass density.

The absence of livestock grazing results in a territorial reduction of *Trifolium subterraneum*- and *Poa bulbosa*-dominated areas and in a density/cover reduction of *Poa bulbosa*-dominated areas. The abandonment of grazing seems to change these pastures to a state where *Poa bulbosa* is less abundant and *Trifolium subterraneum* occupies smaller patches (Set B in the study area).

Environmental and land-use variables such as livestock load, regularity of grazing or livestock permanence and stoniness were the selected by the CCA (with Monte Carlo Permutation test) as the key variables related to the floristic patterns observed in the ordination revealing that grazing variables have influence in the floristic composition of perennial swards of *Poa bulbosa*.

The DCCA results revealed that only a small fraction of the species variation is related to ecological factors. A moderate amount of unexplained variance was obtained, which is a common finding in ordination models (ØKLAND, 1999).

Deep and regular soil tillage and land abandonment to natural succession are decisive factors in the disappearance of these Mediterranean short swards. The control of woody vegetation through grazing or cutting is a fundamental conservation measure in line with SAN MIGUEL (2008) and ICNB (2006).

Their maintenance relies on controlling woody vegetation in order to hamper the process of ecological succession. Cutting woody vegetation is preferable to soil tillage as this second management technique diminishes the abundance of *Poa bulbosa* that may need one to several years to attain the initial state.

In some circumstances these communities are highly enriched in *Helianthemetea guttatae* com-

panion species, namely in situations of great oligotrophy and/or very shallow soils where *Poa bulbosa* has not reached its maximum dominance or does not have conditions to develop. It is thus very frequent to observe mosaics of *Poa bulbosa* communities with *Helianthemetea guttatae* communities.

Mediterranean perennial swards of *Poa bulbosa* are a very important food source for wild rabbit populations. This species composes the diet of over forty species found in its natural range (Portugal, Spain and northwestern Africa (Morocco and Algeria); IUCN, 2011a), including several of the birds of prey nesting in the International Tagus region. The Imperial eagle (*Aquila adalberti*) consumes 40-80% of its diet in rabbits (IUCN, 2011b) and the decline of *Oryctolagus cuniculus* (Conservation Status in Portugal: Near

Threatened; (CABRAL & al., 2005) has been linked to the near extinction of this specialist predator (ZOFIO & VEGA, 2000). Therefore, in Spain, much effort is being made to increase the area of *Poetalia communities* in the habitat of endangered species (SAN MIGUEL, 2008) dependent on the European rabbit.

ACKNOWLEDGEMENTS

This study was supported by the Foundation for Science and Technology (FCT) through the PhD project SFRH/BD/29515/2006. The authors wish to thank Rui Ribeiro and the International Tagus Natural Park for all the help provided while carrying out field work in 2009 and 2010 and Carla Cruz for the revision of the manuscript and for all her valuable comment sand David Tucker for proof-reading the English version.

SYNTAXONOMICAL SCHEME

Syntaxa were named according to the International code of Phytosociological Nomenclature (ICPN), 3rd edition (WEBER & al., 2000).
